1.2 Introduction

The low-cost MC68HC805K3 microcontroller is a member of the M68HC805 Family of microprocessors. This device has 64 bytes of user RAM, 128 bits of personality electronically erasable programmable ROM (PEEPROM), and 928 bytes of user EEPROM. This device is available in the 16-pin plastic dual in-line package (PDIP) and 16-pin small outline integrated circuit (SOIC) package. A functional block diagram of the MC68HC805K3 is shown in [Figure 1-2](#).

1.3 Features

- Low-Cost HC05 Core
- 16-Pin PDIP or SOIC Package
- 928 Bytes of User EEPROM (Including Eight Bytes of User Vectors)
- 64 Bytes of User RAM
- 128 Bits of Personality EEPROM (Not Memory Mapped) Programmed using User Software or during User EEPROM Programming
- On-Chip Charge Pump for In-Circuit Programming of the Personality EEPROM at 3.0 to 5.5 Vdc.
- 8-Bit Free-Running Timer
- 4-Stage Selectable Real-Time Interrupt Generator
- 10 Bidirectional Input/Output (I/O) Lines Including:
 - 8 mA Sink Capability on Four I/O Pins (PA7–PA4)
 - Mask Option Register Bit for Software Programmable Pulldowns on All I/O Pins
 - Mask Option Register Bit for Port Interrupts on Four I/O Pins (PA3–PA0) (Keyboard Scan Feature)
- IRQ Interrupt Hardware Mask, Flag Bit, and Request Bit
- Mask Option Register Bit for Sensitivity on IRQ Interrupt (Edge- and Level-Sensitive or Edge-Sensitive Only)
- On-Chip Oscillator (Mask Option Register Bits for Crystal/Ceramic Resonator Oscillator with Internal 2 MΩ Resistor, and 2-Pin or 3-Pin Resistor Capacitor (RC) Oscillator)
- Mask Option Register Bit for Reduced Startup Delay Time with RC Oscillator Options
- Mask Option Register Bit for Computer Operating Properly (COP) Watchdog System
- Power-Saving Stop and Wait Mode Instructions

- Mask Option Register Bit to Convert STOP Instruction to Halt Mode
- Illegal Address Reset
- Internal Steering Diode and Pullup Resistor on $\overline{\text{RESET}}$ Pin to V_{DD}
- Internal $\overline{\text{RESET}}$ Pin Pulldown from COP Watchdog and ILADR

NOTE: A line over a signal name indicates an active low signal. For example, RESET is active high and $\overline{\text{RESET}}$ is active low.

Any reference to voltage, current, or frequency specified in the following sections refers to the nominal values. The exact values and their tolerance or limits are specified in [Section 12. Electrical Specifications](#).

1.4 Mask Option Register

The MC68HC805K3 contains these nine programmable options:

1. COP Watchdog Timer (Enable or Disable)
2. IRQ Triggering (Edge-Sensitive or Edge- and Level-Sensitive)
3. Port A Interrupts (Enable or Disable)
4. Port Software Programmable Pulldowns (Enable or Disable)
5. STOP Instruction (Enable or Disable)
6. Oscillator Type (Crystal/Ceramic Resonator or RC)
7. RC Oscillator Type (2-Pin or 3-Pin)
8. RC Oscillator Startup Delay (4064 or 16 f_{OP} Cycles)
9. User EEPROM and PEEP Security (Enable or Disable)

NOTE: The startup delay of 16 f_{OP} cycles and the crystal/ceramic resonator oscillator should not be selected together.

1.5 Pin Assignments

The MC68HC805K3 is available in 16-pin SOIC and PDIP packages. The pin assignments for these packages are shown in **Figure 1-1**.

Figure 1-1. MC68HC805K3 Pin Assignments

1.6 MCU Structure

The overall block diagram of the MC68HC805K3 is shown in **Figure 1-2**.

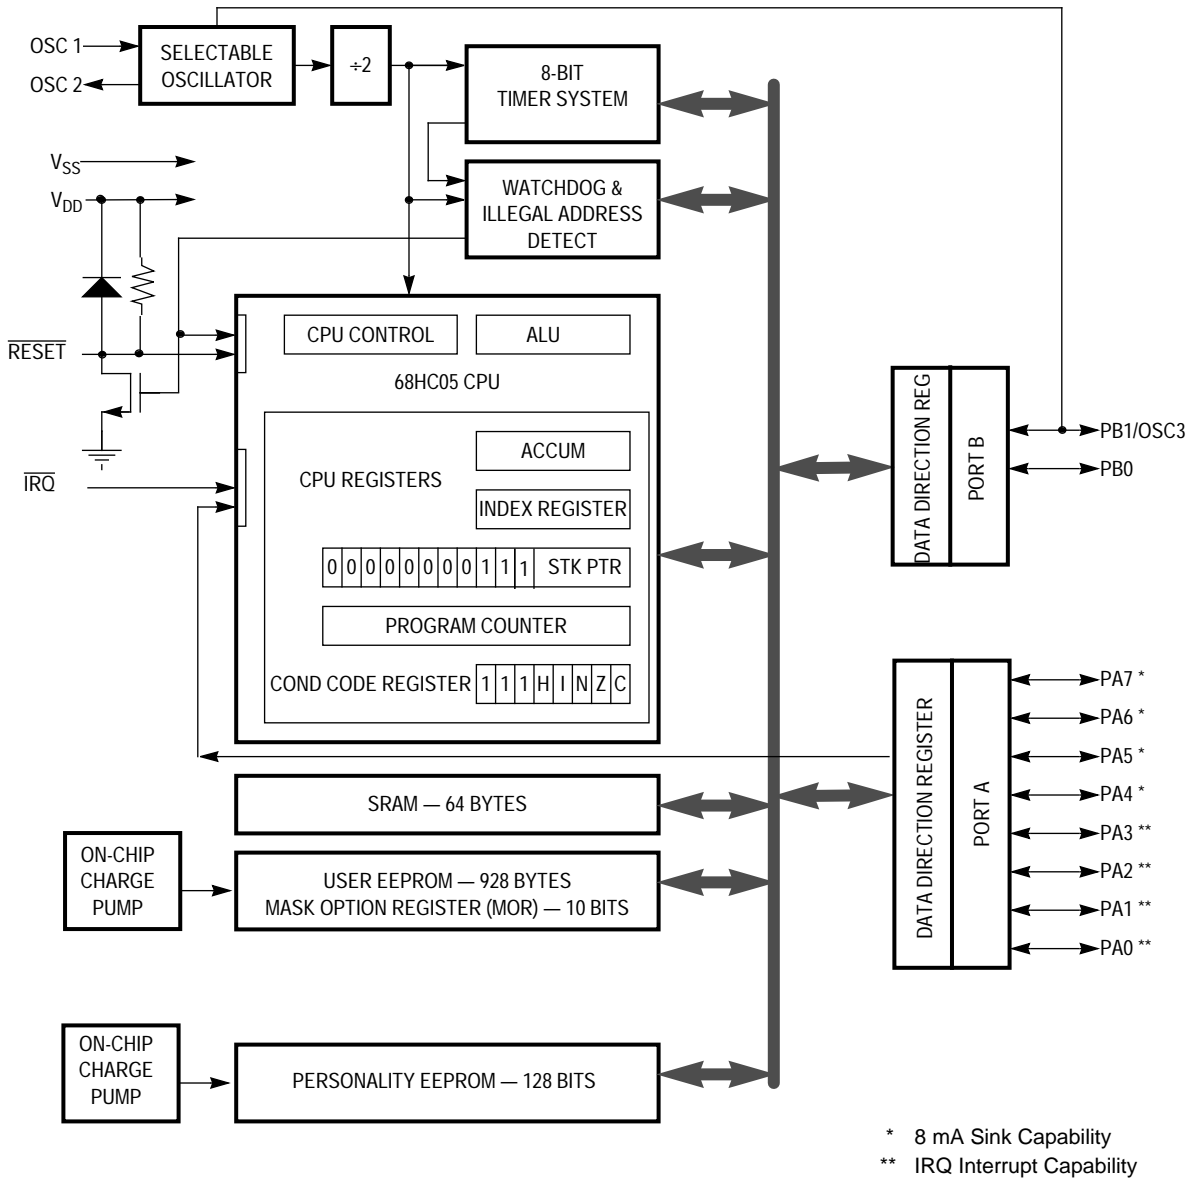

Figure 1-2. MC68HC805K3 Block Diagram

1.7 Functional Pin Description

The following paragraphs give a description of the general function of each pin.

1.7.1 V_{DD} and V_{SS}

Power is supplied to the MCU through V_{DD} and V_{SS} . V_{DD} is the positive supply and V_{SS} is ground. The MCU operates from a single power supply.

Rapid signal transitions occur on the MCU pins. The short rise and fall times place very high short-duration current demands on the power supply. To prevent noise problems, special care should be taken to provide good power supply bypassing at the MCU by using bypass capacitors with high-frequency characteristics that are positioned as close to the MCU as possible.

1.7.2 OSC1 and OSC2

The OSC1 and OSC2 pins are the connections for the 2-pin on-chip oscillator. The OSC1 and OSC2 pins also can be used in conjunction with the PB1/OSC3 pin to create a more stable 3-pin RC oscillator. The OSC1, OSC2, and PB1/OSC3 pins can accept these sets of components:

1. A crystal, as shown in [Figure 1-3\(a\)](#)
2. A ceramic resonator, as shown in [Figure 1-3\(a\)](#)
3. An external resistor and capacitor using two pins, as shown in [Figure 1-3\(b\)](#)
4. An external resistor and capacitor using three pins, as shown in [Figure 1-3\(c\)](#)
5. An external clock signal, as shown in [Figure 1-3\(d\)](#)

The frequency, f_{OSC} , of the oscillator or external clock source is divided by two to produce the internal operating frequency f_{OP} . The oscillator type is selected by two mask option register bits.

1.7.2.1 2-Pin Crystal Oscillator

The circuit in **Figure 1-3(a)** shows a typical 2-pin oscillator circuit for an AT-cut, parallel resonant crystal. The crystal manufacturer's recommendations should be followed, since the crystal parameters determine the external component values required to provide maximum stability and reliable startup. The load capacitance values used in the oscillator circuit design should include all stray capacitances. The crystal and components should be mounted as close as possible to the pins for startup stabilization and to minimize output distortion. An internal startup resistor of approximately 2 MΩ is provided between OSC1 and OSC2 when the crystal/ceramic resonator oscillator option is used.

Figure 1-3. Oscillator Connections

1.7.2.2 2-Pin Ceramic Resonator Oscillator

In cost-sensitive applications, a ceramic resonator can be used instead of the crystal. The circuit in **Figure 1-3(a)** is for a ceramic resonator also. The resonator manufacturer's recommendations should be followed, since the resonator parameters determine the external component values required for maximum stability and reliable starting. The load capacitance values used in the oscillator circuit design should include all stray capacitances. The ceramic resonator and components should be mounted as close as possible to the pins for startup stabilization and to minimize output distortion. An internal startup resistor of approximately 2 M Ω is provided between OSC1 and OSC2 for the crystal/ceramic resonator oscillator mask option register bit.

1.7.2.3 2-Pin RC Oscillators

The 2-pin RC oscillator configuration can be used for very low-cost applications. With this option, a resistor must be connected between the two oscillator pins and a capacitor must be connected from the OSC1 pin to V_{SS}, as shown in **Figure 1-3(b)**. The signal on the OSC2 pin is a square wave and the signal on the OSC1 pin approximates a triangular wave.

The 2-pin RC oscillator is selected by programming bit 5 ("RC") of the mask option register located at \$0012. Bit 6 ("Pin 3") should NOT be programmed when using the 2-pin oscillator.

The 2-pin RC oscillator is optimized for operation at 500 kHz. This oscillator can be used at higher or lower frequencies with degraded accuracy over temperature, supply voltage, and/or device processing variations. The internal startup resistor of approximately 2 M Ω is **not** connected between OSC1 and OSC2 when the 2-pin RC oscillator mask option register bit is selected.

1.7.2.4 3-Pin RC Oscillator

Another low cost, but more accurate, type of RC oscillator is the 3-pin configuration utilizing the PB1/OSC3 pin. With this option, a resistor must be connected between the OSC1 and OSC2 pins and a capacitor must be connected between the OSC1 and PB1/OSC3 pins, as shown in **Figure 1-3(c)**. This 3-pin RC oscillator is more accurate than the 2-pin RC oscillator with respect to temperature, supply voltage, and/or device processing variations. The signal on the OSC2 and PB1/OSC3 pins is a square wave and the signal on the OSC1 pin approximates a triangular wave.

Selection of the 3-bit RC oscillator requires programming two bits in the mask option register located at \$0012. Bit 5 ("RC"), when programmed, enables the RC oscillator. Bit 6 ("Pin 3"), when programmed along with bit 5, selects the 3-pin oscillator configuration.

The 3-pin RC oscillator is optimized for operation at 500 kHz. This oscillator can be used at higher or lower frequencies with degraded accuracy over temperature, supply voltage, and/or device processing variations. The internal startup resistor of approximately 2 M Ω is **not** connected between OSC1 and OSC2 when the 3-pin RC oscillator mask option register bit is selected. The typical external components for a 500-kHz oscillator are a 20-k Ω resistor and a 25- to 30-pF capacitor.

NOTE: *Capacitors used with the RC oscillators should have minimal leakage. Electrolytic or tantalum capacitors should not be used because they degrade the temperature performance of the oscillator due to excessive variation in their leakage.*

1.7.2.5 External Clock

An external clock from another CMOS-compatible device can be connected to the OSC1 input, with the OSC2 input not connected, as shown in **Figure 1-3(d)**. This configuration is possible regardless of whether the oscillator is set up for crystal/ceramic resonator, 2-pin RC, or 3-pin RC operation. However, if the 3-pin RC oscillator is selected, the PB1/OSC3 pin also must be left unconnected.

1.7.3 Reset ($\overline{\text{RESET}}$)

This pin can be used as an input to reset the MCU to a known startup state by pulling the pin to the low state. The $\overline{\text{RESET}}$ pin contains a steering diode to discharge any voltage on the pin to V_{DD} when the power is removed. The $\overline{\text{RESET}}$ pin contains an internal pullup resistor to V_{DD} of approximately 100 k Ω to allow the $\overline{\text{RESET}}$ pin to be left unconnected for low-power applications. The $\overline{\text{RESET}}$ pin contains an internal Schmitt trigger to improve its noise immunity as an input.

The $\overline{\text{RESET}}$ pin has an internal pulldown device that pulls the $\overline{\text{RESET}}$ pin low when there is an internal COP watchdog or an illegal address reset. Refer to [Section 5. Resets](#).

1.7.4 Maskable Interrupt Request ($\overline{\text{IRQ}}$)

The $\overline{\text{IRQ}}$ input pin drives the asynchronous IRQ interrupt function of the CPU. The IRQ interrupt function has a mask option register bit to select either negative edge-sensitive triggering or both negative edge-sensitive and low level-sensitive triggering. If the option is selected to include level-sensitive triggering, the $\overline{\text{IRQ}}$ pin requires an external resistor to V_{DD} if “wired-OR” operation is desired. If the $\overline{\text{IRQ}}$ pin is not used, it must be tied to the V_{DD} supply.

NOTE: *Each of the PA0 through PA3 I/O pins can be connected through an OR gate to the IRQ interrupt function by a common mask option. This capability allows keyboard scan applications where the transitions or levels on the I/O pins behave the same as the $\overline{\text{IRQ}}$ pin, except that the logic level is inverted. The edge or level sensitivity selected by the mask option register bit for the $\overline{\text{IRQ}}$ pin also applies to the I/O pins ORed to create an IRQ signal.*

The $\overline{\text{IRQ}}$ pin contains an internal Schmitt trigger to improve noise immunity. For more details, see [Section 4. Interrupts](#).

1.7.5 PA0 through PA7

These eight I/O lines comprise port A. The state of any pin is software programmable and all port A lines are configured as inputs during power-on or reset. The four upper-order I/O pins (PA4 through PA7) are capable of sinking higher currents. The four lower-order I/O pins (PA0 through PA3) can be connected via an internal OR gate to the IRQ interrupt function by a mask option register bit. All the port A pins can have software programmable pulldown devices provided by another mask option bit. See [Section 7. Parallel Input/Output](#) for more details on the I/O ports.

1.7.6 PB0

The state of the PB0 pin is software programmable and is configured as an input during power-on or reset. This pin can have a software programmable pulldown device provided by a mask option register bit. See [Section 7. Parallel Input/Output](#) for more details on the I/O ports.

1.7.7 PB1/OSC3

The state of the PB1/OSC3 pin is software programmable and is configured as an input during power-on or reset except when the 3-pin RC oscillator configuration is selected by a pair of mask option register bits. This pin can have a software programmable pulldown device provided by a mask option. See [Section 7. Parallel Input/Output](#) for more details on the I/O ports.

2.2 Introduction

The MC68HC805K3 has several input/output (I/O) features, 64 bytes of user read-only memory (RAM), 128 bits of personality user electronically erasable programmable read-only memory (PEEPROM), and 928 bytes of user EEPROM, which are all active in the single-chip mode as shown in **Figure 2-1**.

Figure 2-1. MC68HC805K3 Single-Chip Mode Memory Map

2.3 I/O and Control Registers

The I/O and status/control registers reside in locations \$0000–\$001F. The overall organization of these registers is shown in **Figure 2-2**.

The bit assignments for each register are shown in **Figure 2-3** and **Figure 2-4**. Reading unimplemented bits returns unknown states, and writing to unimplemented bits has no effect.

Figure 2-4. MC68HC805K3 I/O Registers \$0010–\$001F

2.4 Random-Access Memory (RAM)

The total RAM consists of 64 bytes (including the stack) at locations \$00C0 through \$00FF. The stack pointer can access 32 locations from \$00E0 to \$00FF. The stack begins at address \$00FF and proceeds down to \$00E0. Using the stack area for data storage or temporary work locations requires care to prevent it from being overwritten due to stacking from an interrupt or subroutine call.

2.5 User Electronically Erasable Programmable Read-Only Memory

A total of 928 bytes of user EEPROM is on chip. This includes 160 bytes in page zero from locations \$0020 through \$00BF, 760 bytes of user EEPROM with locations \$0100 through \$03F7 for user program storage, and 8 bytes for user vectors at locations \$03F8 through \$03FF.

2.6 Mask Option Registers (MOR) \$0012 and \$0013

The mask option registers consist of 10 EEPROM bits located at \$0012 and \$0013. These registers hold the option bits for the interrupt sensitivity, COP enable/disable, enable pulldowns/interrupt on port A and port B, interrupts via the lower four bits of port A, STOP instruction as HALT, oscillator type, and security. When in the erased state, the EEPROM cells will read as logic zeros. These registers are refreshed at a rate of 1 ms (typical) using an internal ring oscillator. During STOP and MOR programming, the MOR1 and MOR2 will not be refreshed.

3.1 Contents

3.2	Introduction	35
3.3	Registers	36
3.3.1	Stack Pointer (SP)	37
3.3.2	Program Counter (PC)	37

3.2 Introduction

The MC68HC805K3 has a 1024-byte memory map. Therefore, it uses only the lower 10 bits of the address bus. In the following discussion, the upper six bits of the address bus can be ignored. Also, by using a mask option register bit, the STOP instruction can be converted from acting as the normal STOP instruction. The stack area also is reduced to 32 bytes due to the limited amount of RAM. Therefore, the stack pointer is reduced to only five bits, only decrements down to \$00E0, and then wraps around to \$00FF. All other instructions and registers behave as described in *M6805 HMOS/M146805 CMOS Family User's Manual* (M6805UM/AD3).

3.3 Registers

The MCU contains five registers that are hard-wired within the CPU and are not part of the memory map. These five registers are shown in [Figure 3-1](#).

Figure 3-1. M68HC05 Programming Model

For a more complete description of the M68HC05 CPU functions, refer to *M6805 HMOS, M146805 CMOS Family User's Manual* (M6805UM(AD3)), *HC05 Applications Guide* (M68HC05AG/AD), or *Understanding Small Microcontrollers* (M68HC05TB/D). Any specific differences in the operation of all CPU registers or bits is described in the following sections.

3.3.1 Stack Pointer (SP)

The stack pointer shown in **Figure 3-1** is a 16-bit register internally. In devices with memory maps less than 64 Kbytes, the unimplemented upper address lines are ignored. The stack pointer contains the address of the next free location on the stack. When accessing memory, the 11 most significant bits are permanently set to 00000000111. The five least significant register bits are appended to these 11 fixed bits to produce an address within the range of \$00FF to \$00E0. Subroutines and interrupts may use up to 32 (\$20) locations. If 32 locations are exceeded, the stack pointer wraps around to \$00FF and writes over the previously stored information.

3.3.2 Program Counter (PC)

The program counter shown in **Figure 3-1** is a 16-bit register internally. The program counter contains the address of the next instruction or operand to be fetched. The six most significant bits of the program counter are ignored internally and appear as 000000 when stacked onto the RAM.

Section 4. Interrupts

4.1 Contents

4.2	Introduction	39
4.3	CPU Interrupt Processing	40
4.4	Reset Interrupt Sequence	42
4.5	Software Interrupt (SWI)	42
4.6	Hardware Interrupts	43
4.6.1	External Interrupt (IRQ)	43
4.6.2	IRQ Status/Control Register (ISCR)	45
4.6.3	Port Interrupts (PA0–PA3)	46
4.6.4	Timer Interrupt (TIMER)	47

4.2 Introduction

The MCU can be interrupted four different ways:

1. Non-maskable software interrupt instruction (SWI)
2. External asynchronous interrupt ($\overline{\text{IRQ}}$)
3. External interrupt via IRQ on PA0-PA3 (enabled by a mask option register bit)
4. Internal timer interrupt (TIMER)

4.3 CPU Interrupt Processing

Interrupts cause the processor to save register contents on the stack and to set the interrupt mask (I bit) to prevent additional interrupts. Unlike RESET, hardware interrupts do not cause the current instruction execution to be halted, but are considered pending until the current instruction is complete.

If interrupts are not masked (I bit in the CCR is clear) and the corresponding interrupt enable bit is set, the processor proceeds with interrupt processing. Otherwise, the next instruction is fetched and executed. If an interrupt occurs, the processor completes the current instruction, stacks the current CPU register states, sets the I bit to inhibit further interrupts, and finally checks the pending hardware interrupts. If more than one interrupt is pending following the stacking operation, the interrupt with the highest vector location, shown in [Table 4-1](#), is serviced first. The SWI is executed the same as any other instruction, regardless of the I-bit state.

When an interrupt is to be processed, the CPU fetches the address of the appropriate interrupt software service routine from the vector table at locations \$03F8 through \$03FF as defined in [Table 4-1](#).

Table 4-1. Vector Addresses for Interrupts and Reset

Register	Flag Name	Interrupts	CPU Interrupts	Vector Addresses
N/A	N/A	Reset	RESET	\$03FE-\$03FF
N/A	N/A	Software	SWI	\$03FC-\$03FD
ISCR	IRQF	External Interrupt	IRQ	\$03FA-\$03FB
TSCR	TOF	Timer Overflow	TIMER	\$03F8-\$03F9
TSCR	RTIF	Real Time Interrupt	TIMER	\$03F8-\$03F9

An RTI instruction is used to signify when the interrupt software service routine is complete. The RTI instruction causes the register contents to be recovered from the stack and normal processing to resume at the next instruction that was to be executed when the interrupt took place. **Figure 4-1** shows the sequence of events that occurs during interrupt processing. **Figure 4-2** shows the stacking and unstacking order into the RAM that is associated with an interrupt service routine.

Figure 4-1. Interrupt Processing Flowchart

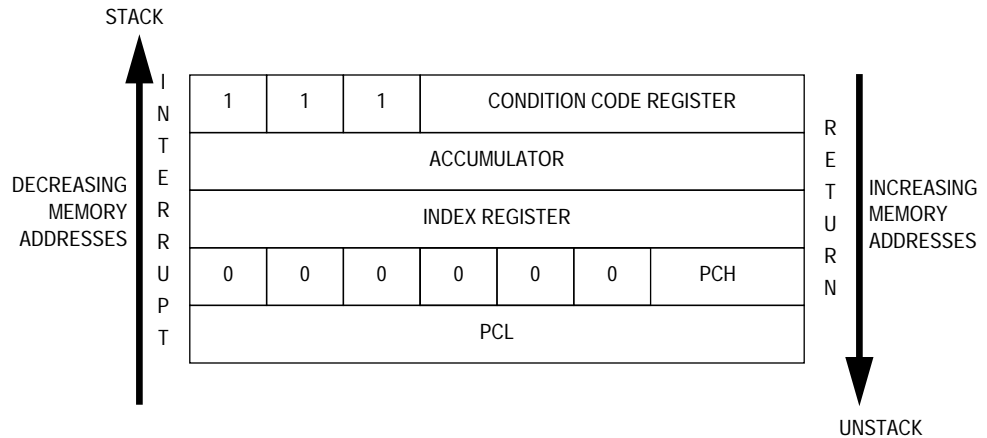

Figure 4-2. Interrupt Stacking Order

4.4 Reset Interrupt Sequence

The reset function is not in the strictest sense an interrupt; however, it is acted upon in a similar manner. A low-level input on the $\overline{\text{RESET}}$ pin or an internally generated RST signal causes the program to vector to its starting address, which is specified by the contents of memory locations \$03FE and \$03FF. The I bit in the condition code register also is set. The MCU is configured to a known state during this type of reset, as described in [Section 5. Resets](#).

4.5 Software Interrupt (SWI)

The SWI is an executable instruction and a non-maskable interrupt since it is executed regardless of the state of the I bit in the CCR. If the I bit is zero (interrupts enabled), the SWI instruction executes after interrupts that were pending before the SWI was fetched or before interrupts generated after the SWI was fetched. The interrupt service routine address is specified by the contents of memory locations \$03FC and \$03FD.

4.6 Hardware Interrupts

All hardware interrupts except RESET are maskable by the I bit in the CCR. If the I bit is set, all hardware interrupts (internal and external) are disabled. Clearing the I bit enables the hardware interrupts. The two types of hardware interrupts are explained in the following sections.

4.6.1 External Interrupt ($\overline{\text{IRQ}}$)

The $\overline{\text{IRQ}}$ pin provides an asynchronous interrupt to the CPU. A block diagram of the IRQ function is shown in **Figure 4-3**.

The $\overline{\text{IRQ}}$ pin is one source of an IRQ interrupt, and a mask option register bit is available to enable the four lower order port A pins (PA0 through PA3) to act as other IRQ interrupt sources. All of these sources are combined into a single ORing function that is latched by the IRQ latch.

The IRQ latch is set on the falling edge of the $\overline{\text{IRQ}}$ pin or on the rising edge of a PA0 through PA3 pin, if port A interrupts have been enabled by the mask option register bit.

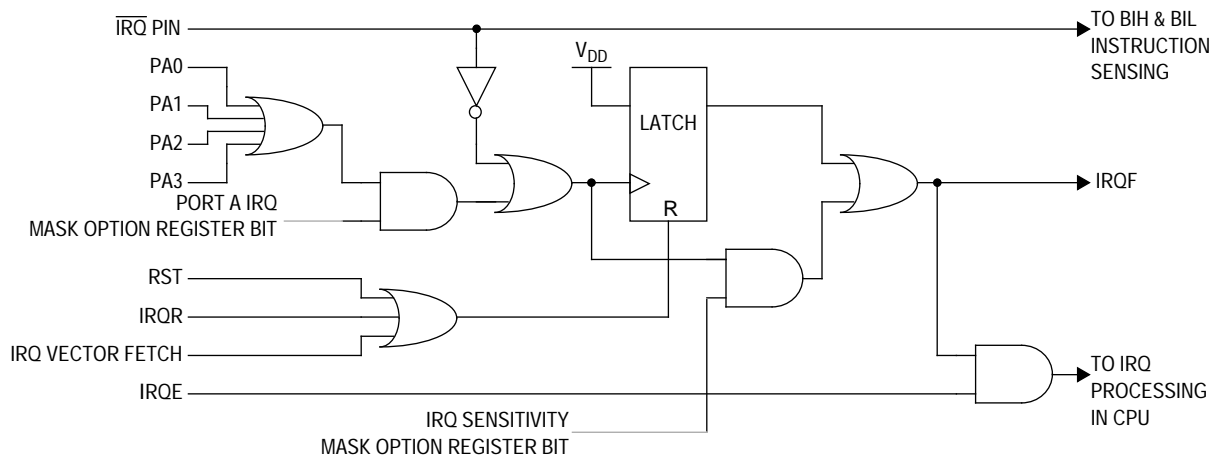

Figure 4-3. IRQ Function Block Diagram

If the mask option for **edge-sensitive only** IRQ is used, only the IRQ latch output can activate an IRQF flag which creates a request to the CPU to generate the IRQ interrupt sequence. This makes the IRQ interrupt sensitive to these cases:

- If the port A interrupts are **disabled** by a mask option register bit, only a falling edge on the $\overline{\text{IRQ}}$ pin initiates an IRQ interrupt.
- If the port A interrupts are **enabled** by a mask option register bit, these conditions initiate an IRQ interrupt:
 - A falling edge on the $\overline{\text{IRQ}}$ pin with all the PA0 through PA3 pins at a low level
 - A rising edge on one PA0 through PA3 pin with all other PA0 through PA3 pins at a low level and the $\overline{\text{IRQ}}$ pin at a high level

If the mask option register bit for **edge- and level-sensitive** IRQ is used, the active high state of the IRQ latch input also can activate an IRQF flag, which creates a request to the CPU to generate the IRQ interrupt sequence. This makes the IRQ interrupt sensitive to these cases:

- If the port A Interrupts are **disabled** by a mask option register bit, only these conditions initiate an IRQ interrupt:
 - A low level on the $\overline{\text{IRQ}}$ pin
 - Falling edge on the $\overline{\text{IRQ}}$ pin
- If the port A interrupts are **enabled** by a mask option register bit, these conditions initiate an IRQ interrupt:
 - A low level on the $\overline{\text{IRQ}}$ pin with all the PA0 through PA3 pins at a low level.
 - Falling edge on the $\overline{\text{IRQ}}$ pin with all the PA0 through PA3 pins at a low level.
 - High level on any one of the PA0 through PA3 pins with the $\overline{\text{IRQ}}$ pin at a high level.
 - Rising edge on any PA0 through PA3 pin with all other PA0 through PA3 pins at a low level and the $\overline{\text{IRQ}}$ pin at a high level.

The IRQE enable bit controls whether an active IRQF flag can generate an IRQ interrupt sequence. This interrupt is serviced by the interrupt service routine located at the address specified by the contents of \$03FA and \$03FB.

Entering the interrupt service routine automatically clears the IRQ latch. The IRQ interrupt service routine also may clear the IRQ latch by writing a logic one to the IRQR acknowledge bit in the ISCR. As long as the output state of the IRQF flag bit is active, the CPU continuously re-enters the IRQ interrupt sequence following an RTI instruction until the active state is removed or the IRQE enable bit is cleared.

4.6.2 IRQ Status/Control Register (ISCR)

The IRQ interrupt function is controlled by the ISCR located at \$000A as shown in **Figure 4-4**. All unused bits in the ISCR read as logic zeros. A reset clears the IRQF bit and sets the IRQE bit.

\$000A	Bit 7	6	5	4	3	2	1	Bit 0
Read:	IRQE	0	0	0	IRQF	0	0	0
Write:				R			IRQR	
Reset:	1	0	0	0	0	0	0	0

= Unimplemented
 R = Reserved

Figure 4-4. IRQ Status/Control Register

IRQR — IRQ Interrupt Acknowledge

The IRQR acknowledge bit clears an IRQ interrupt request by clearing the IRQ latch. If the IRQ latch is set again while in the IRQ service routine (before an RTI instruction is executed), the CPU re-enters the IRQ interrupt service routine unless the IRQ latch is cleared. Writing a logic one to the IRQR acknowledge bit clears the IRQ latch. Writing a logic zero to the IRQR acknowledge bit has no effect on the IRQ latch. The IRQR acknowledge bit always reads as a logic zero.

IRQF — IRQ Interrupt Request

The IRQF flag bit indicates that an IRQ request is pending. Writing to the IRQF flag bit has no effect on it. The IRQF flag bit is cleared automatically when the IRQ vector is fetched and the service routine is entered. The IRQF flag bit also can be cleared by writing a logic one to the IRQR acknowledge bit to clear the IRQ latch and also condition

the external IRQ sources to be inactive if the edge- and level-sensitive mask option register bit is selected. In this way, any additional setting of the IRQF flag bit while in the service routine can be ignored by clearing the IRQF flag bit just before exiting the service routine. If the IRQF flag bit is set again while in the IRQ service routine, the CPU re-enters the IRQ interrupt sequence unless the IRQF flag bit is cleared. The IRQF flag bit is cleared by reset.

IRQE — IRQ Interrupt Enable

The IRQE bit enables or disables the IRQF flag bit to initiate an IRQ interrupt sequence. If the IRQE enable bit is set, the IRQF flag bit can generate an interrupt sequence. If the IRQE enable bit is cleared, the IRQF flag bit cannot generate an interrupt sequence. Reset sets the IRQE enable bit, thereby enabling IRQ interrupts once the I bit is cleared. Execution of the STOP or WAIT instructions causes the IRQE bit to be set to allow the external IRQ to exit these modes. In addition, reset also sets the I bit, which masks all interrupt sources.

NOTE: *If the I bit is cleared, any instruction that sets the IRQE enable bit when the IRQF flag bit is already set initiates an IRQ interrupt sequence immediately after that instruction.*

4.6.3 Port Interrupts (PA0–PA3)

The IRQ interrupt also can be triggered by inputs to PA0 through PA3 port pins as described in [4.6.1 External Interrupt \(IRQ\)](#) if the port interrupts mask option register bit is used. If enabled, the lower four bits of port A can activate the IRQ interrupt function and the interrupt operation is the same as the input to the \overline{IRQ} pin. The mask option register bit allows all of these input pins to be ORed with the input present on the \overline{IRQ} pin. All PA0 through PA3 pins must be selected as a group and as an additional IRQ interrupt source. All the port A interrupt sources also are controlled by the IRQE enable bit.

NOTE: *The BIH and BIL instructions apply only to the level on the \overline{IRQ} pin itself and not to the output of the logic OR gate with PA0 through PA3 pins. The state of the individual port A pins can be checked by reading the appropriate port A pins as inputs.*

NOTE: *If port A interrupts are enabled, the state of PA0 through PA3 pins may cause an IRQ interrupt regardless of whether these pins are configured as inputs or outputs. (See [Section 7. Parallel Input/Output.](#))*

4.6.4 Timer Interrupt (TIMER)

The timer interrupt is generated by the 8-bit timer when either a timer overflow or a real-time interrupt has occurred, as described in [Section 8. 8-Bit Timer](#). The interrupt flags and enable bits for the timer interrupts are in the timer status/control register (TSCR) located at \$0008. The I bit in the CCR must be clear for the timer interrupt to be enabled. Either of these two interrupts vector to the same interrupt service routine located at the address specified by the contents of memory locations \$03F8 and \$03F9.

Section 5. Resets

5.1 Contents

5.2	Introduction	49
5.3	External Reset ($\overline{\text{RESET}}$)	50
5.4	Internal Resets	50
5.4.1	Power-On Reset (POR)	50
5.4.2	Computer Operating Properly Reset (COPR)	51
5.4.3	Illegal Address Reset (ILADR)	51

5.2 Introduction

The MCU can be reset from four sources: one external input and three internal restart conditions. The $\overline{\text{RESET}}$ pin is an input with a Schmitt trigger, as shown in **Figure 5-1**. All the internal peripheral modules that drive external pins are reset by the synchronous reset signal (RST) coming from a latch, which is synchronized to the PH2 bus clock and set by any of the four reset sources.

NOTE: *Activation of the RST signal generally is referred to as a reset of the device, unless otherwise specified.*

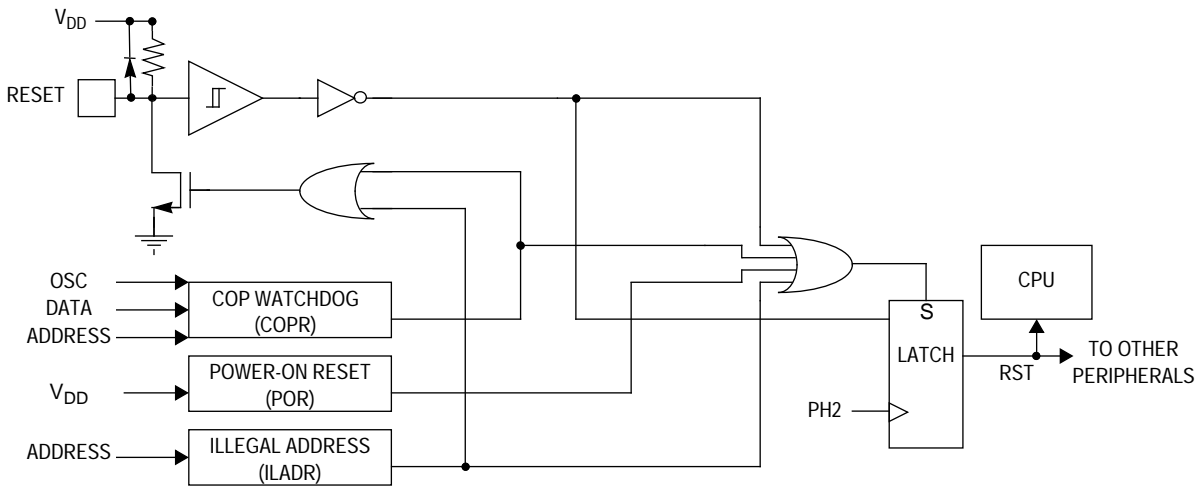

Figure 5-1. Reset Block Diagram

5.3 External Reset ($\overline{\text{RESET}}$)

The $\overline{\text{RESET}}$ pin is the only external source of a reset. This pin is connected to a Schmitt trigger input gate to provide noise immunity. This external reset occurs whenever the $\overline{\text{RESET}}$ pin is pulled low and remains in reset until the $\overline{\text{RESET}}$ pin rises to a logic one. This active low input generates the RST signal and resets the CPU and peripherals.

5.4 Internal Resets

The three internally generated resets are the initial power-on reset function, the COP watchdog timer reset, and the illegal address detector reset.

5.4.1 Power-On Reset (POR)

The internal POR is generated on power-up of the internal CPU to allow the clock oscillator to stabilize. The POR is strictly for power turn-on conditions and is not able to detect a drop in the power supply voltage (a “brown-out” condition). After the oscillator becomes active, a mask

option register bit selects an oscillator stabilization delay of 16 or 4064 cycles of the internal processor bus clock (PH2).

The POR generates the RST signal that resets the CPU. If any other reset function is active at the end of this stabilization delay, the RST signal remains in the reset condition until the other reset condition(s) end(s).

5.4.2 Computer Operating Properly Reset (COPR)

A COP watchdog timer can be enabled by a mask option register bit. The internal COP reset (COPR) is generated automatically by a timeout of the COP watchdog timer. This timeout occurs if the counter in the COP watchdog timer is not reset (cleared) within a specific time by a user program reset sequence. Refer to [8.4 COP Watchdog Timer](#) for more information on this timeout feature.

The COPR generates the RST signal that resets the CPU and other peripherals. If any other reset function is active at the end of the COPR reset signal, the RST signal remains in the reset condition until the other reset condition(s) end(s).

The COP Watchdog reset activates the internal pulldown device connected to the $\overline{\text{RESET}}$ pin for one cycle of the internal processor bus clock, PH2.

5.4.3 Illegal Address Reset (ILADR)

The internal ILADR reset is generated when an instruction opcode fetch occurs from an address in the I/O address area (\$0000 through \$001F). The ILADR generates the RST signal that resets the CPU and other peripherals. If any other reset function is active at the end of the ILADR reset signal, the RST signal remains in the reset condition until the other reset condition(s) end(s). The ILADR reset activates the internal pulldown device connected to the $\overline{\text{RESET}}$ pin for **one** cycle of the internal processor bus clock, PH2.

Section 6. Operational Modes

6.1 Contents

6.2	Introduction	53
6.3	Low-Power Modes	53
6.3.1	Stop Mode	53
6.3.2	Halt Mode	56
6.3.3	Wait Mode	57
6.3.4	COP Watchdog Timer Considerations	57

6.2 Introduction

The MC68HC805K3 is capable of running in one of several operational modes to reduce power consumption.

6.3 Low-Power Modes

The WAIT and STOP/HALT instructions provide two low-power operational modes that reduce the power required for the MCU by stopping various internal clocks and/or the on-chip oscillator. The flow of the stop, halt and wait modes is shown in [Figure 6-1](#).

6.3.1 Stop Mode

The STOP instruction can result in one of two modes of operation depending on its mask option register bit. The mask option register bit can make the STOP instruction operate the same as the STOP instruction in other M68HC05 Family members and place the device in stop mode. Or the mask option register bit can make the STOP instruction behave like a WAIT instruction (except that the restart time involves a delay) and place the device in halt mode.

The mask option register bit enabling the execution of the STOP instruction places the MCU in its lowest power consumption mode. In stop mode, the internal oscillator is turned off, halting all internal processing, including the COP watchdog timer.

When the CPU enters stop mode, the interrupt flags (TOF and RTIF) and the interrupt enable bits (TOFE and RTIE) in the TSCR are cleared by internal hardware to remove any pending timer interrupt requests and to disable any further timer interrupts. Execution of the STOP instruction automatically clears the I bit in the condition code register and sets the IRQE enable bit in the IRQ status/control register so that the IRQ external interrupt is enabled. All other memory and registers, including the other bits in the TSCR, remain unaltered.

The MCU can be brought out of stop mode only by an IRQ external interrupt, an IRQ from port A (if mask option register bit is enabled), or an externally generated RESET. When exiting stop mode, the internal oscillator resumes after an oscillator stabilization delay of either 16 or 4064 cycles (depending on mask option register bit state) of the internal processor clock.

NOTE: *If enabled by a mask option register bit, the STOP instruction causes the oscillator to stop and, therefore, disable the COP watchdog timer. If the COP watchdog timer is used and the part is never intended to enter stop mode, the mask option register bit that should be used is the one that disables the STOP instruction and changes the stop mode to the halt mode. See [6.3.4 COP Watchdog Timer Considerations](#) for more details.*

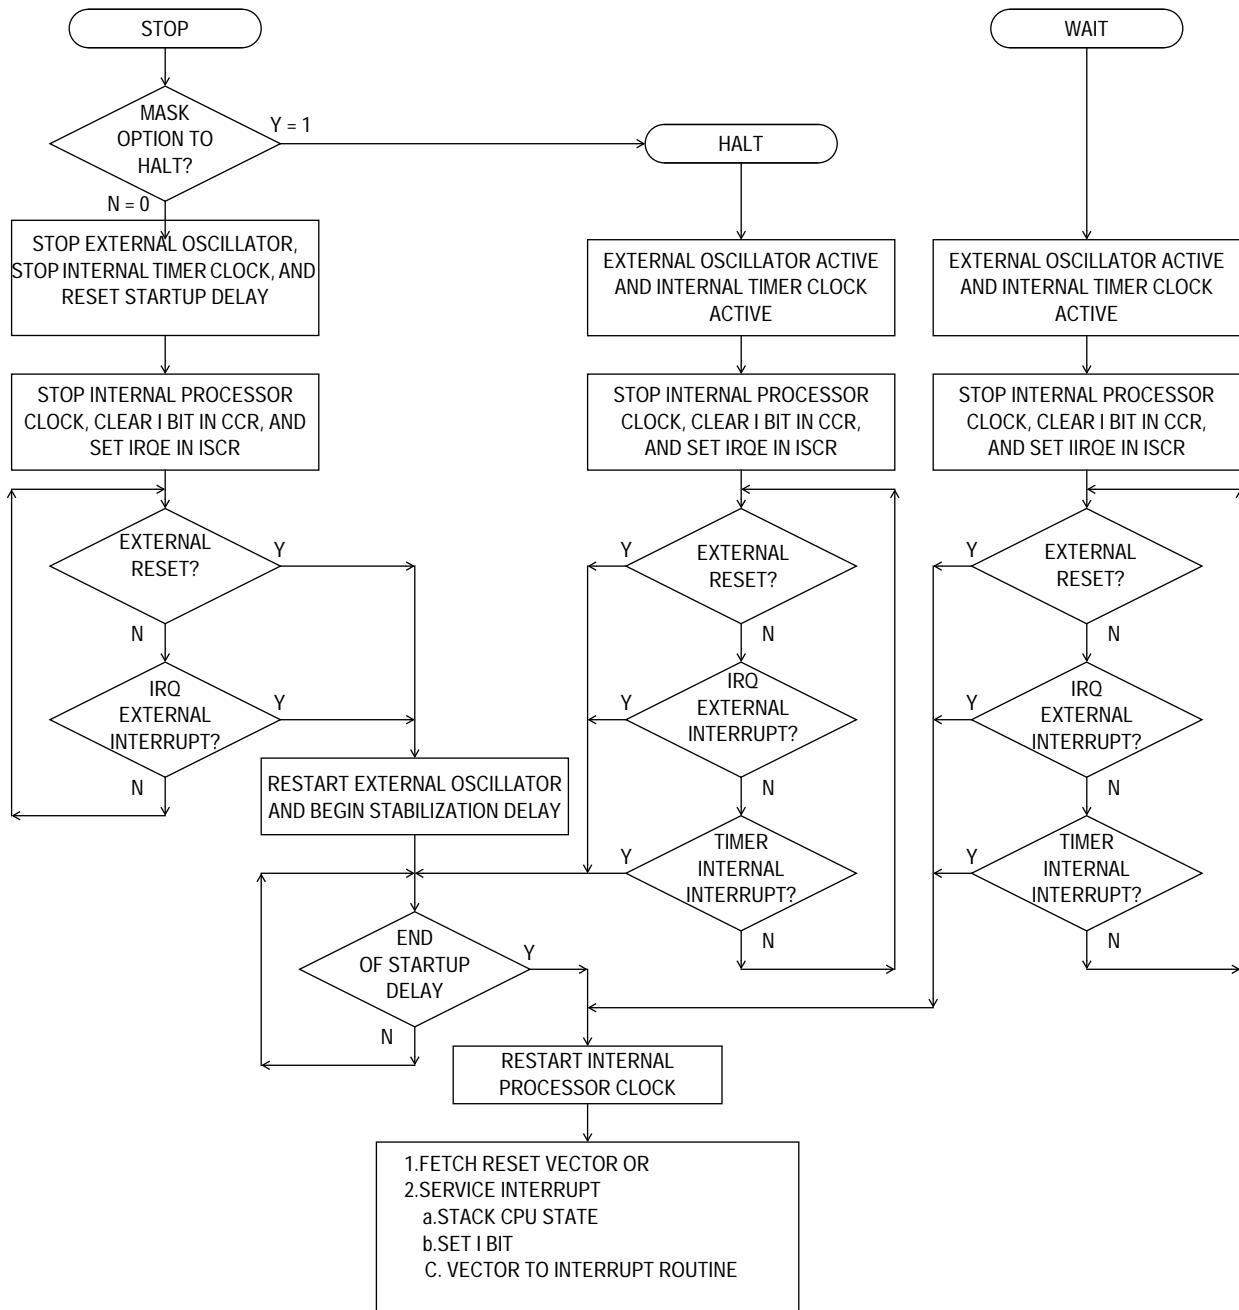

Figure 6-1. Stop/Halt/Wait Flowcharts

6.3.2 Halt Mode

Execution of the STOP instruction with a mask option register bit to disable the stop mode places the MCU in a low-power halt mode, which consumes more power than stop mode. In halt mode, the internal processor clock is halted, suspending all processor and internal bus activity. Internal timer clocks remain active, permitting interrupts to be generated from the timer or a reset to be generated from the COP watchdog timer. Execution of the STOP instruction in the halt mode automatically clears the I bit in the condition code register and sets the IRQE enable bit in the IRQ status/control register so that the IRQ external interrupt is enabled. All other registers, memory, and input/output lines remain in their previous states.

If timer interrupts are enabled, a timer interrupt causes the processor to exit halt mode and resume normal operation. Halt mode also can be exited when an external IRQ or external RESET occurs. When exiting halt mode, the internal processor clock resumes after a variable delay. Depending on the mask option register bit state, the maximum oscillator stabilization delay is 16 or 4064 cycles of the internal processor clock.

Using the mask option register bit to disable the STOP instruction prevents the STOP instruction from halting the oscillator or affecting the COP watchdog timer similar to wait mode. However, the recovery method introduces some startup delay in the processor clock.

NOTE: *Halt mode is not intended for normal use, but is provided to keep the COP watchdog timer active if the STOP instruction opcode is executed inadvertently.*

6.3.3 Wait Mode

The WAIT instruction places the MCU in a low-power wait mode, which consumes more power than stop mode. In wait mode, the internal processor clock is halted, suspending all processor and internal bus activity. Internal timer clocks remain active, permitting interrupts to be generated from the timer or a reset to be generated from the COP watchdog timer. Execution of the WAIT instruction automatically clears the I bit in the condition code register and sets the IRQE enable bit in the IRQ status/control register so that the IRQ external interrupt is enabled. All other registers, memory, and input/output lines remain in their previous states.

If timer interrupts are enabled, a timer interrupt causes the processor to exit wait mode and resume normal operation. Thus, the timer can be used to generate a periodic exit from wait mode. Wait mode also is exited when an external IRQ or RESET occurs.

6.3.4 COP Watchdog Timer Considerations

If the COP watchdog timer is enabled by the mask option register bit, any execution of the STOP instruction (either intentional or inadvertent due to the CPU being disturbed) causes the oscillator to halt and prevent the COP watchdog timer from timing out unless the STOP instruction is disabled by a mask option register bit.

If the mask option register bit is selected to enable the COP watchdog timer, the COP resets the MCU when it times out. Therefore, it is recommended that the mask option register bit be selected to disable the COP watchdog for a system that must have intentional uses of the wait mode for periods longer than the COP timeout period.

7.2 Introduction

In single-chip mode, 10 bidirectional input/output (I/O) lines are arranged as one 8-bit I/O port (port A) and one 2-bit I/O port (port B). The individual bits in these ports are programmable as either inputs or outputs under software control by the data direction registers (DDRs). All port A and port B I/O pins have individual software programmable pulldown devices enabled by a mask option register bit. Some port A pins also have the additional properties of sinking higher current or acting as additional IRQ interrupt input sources. One of the port B pins also may be used as an output for a 3-pin resistor capacitor (RC) oscillator option.

7.3 Port A

Port A is an 8-bit bidirectional port that shares four of its pins with the IRQ interrupt system, as shown in [Figure 7-1](#). Each port A pin is controlled by the corresponding bits in a data direction register, a data register, and a pulldown register.

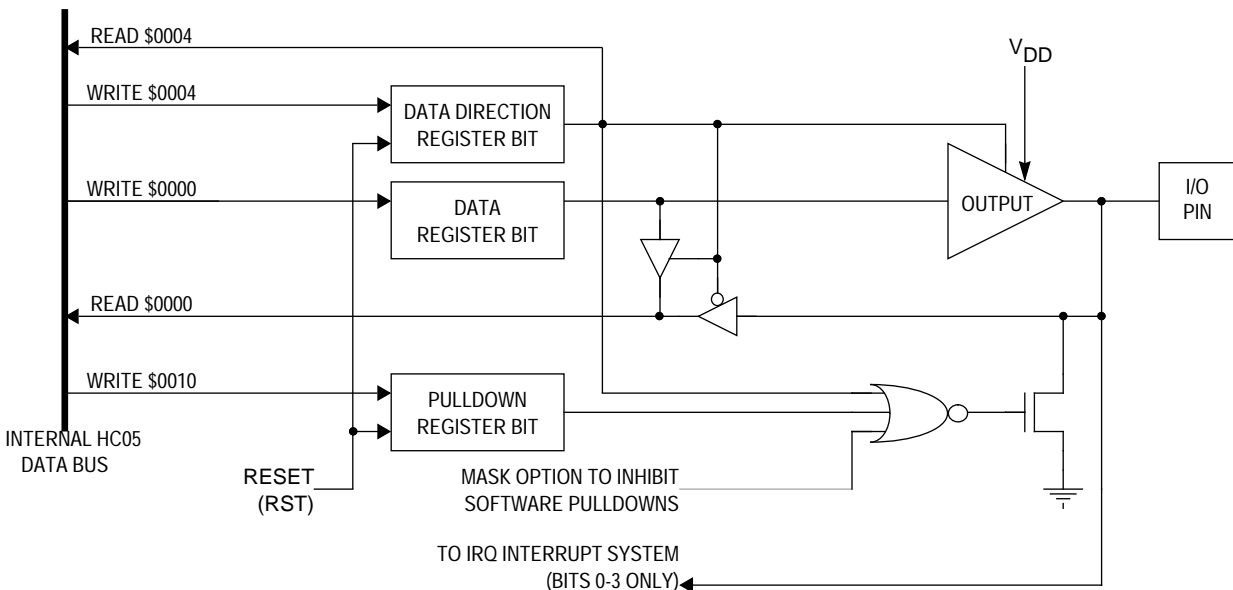

Figure 7-1. Port A I/O Circuitry

The port A DATA register is located at address \$0000. The port A data direction register (DDRA) is located at address \$0004. The port A pulldown register (PDRA) is located at address \$0010. Reset clears both the DDRA and the PDRA. The port A data register is unaffected by reset.

7.3.1 Port A Data Register

Each port A I/O pin has a corresponding bit in the port A data register. When a port A pin is programmed as an output, the state of the corresponding data register bit determines the state of the output pin. When a port A pin is programmed as an input, any read of the port A data register returns the logic state of the corresponding I/O pin, and any write to the port A data register is saved in the data register, but is not applied to the corresponding I/O pin. The port A data register is unaffected by reset. The port A data register is indeterminate after initial power-up.

7.3.2 Port A Data Direction Register

Each port A I/O pin may be programmed as an input by clearing the corresponding bit in the DDRA or programmed as an output by setting the corresponding bit in the DDRA. When a DDRA bit is set, the corresponding pulldown device is disabled. The DDRA can be accessed at address \$0004. The DDRA is cleared by reset.

7.3.3 Port A Pulldown Inhibit Register

All port A I/O pins have software programmable pulldown devices which may be enabled by a mask option register bit. If enabled by mask option register bit, the software programmable pulldowns are activated by clearing their corresponding bit in the PDRA or disabled by setting the corresponding bit in the PDRA. If disabled by a mask option register bit, all pulldowns are disabled. A pulldown on an I/O pin can be activated only if the I/O pin is programmed as an input. Any activated pulldowns on the port A pins are not affected by the V_{DD} supply source to the drivers.

The PDRA is a write-only register and any reads of location \$0010 return undefined results. Since reset clears both the DDRA and the PDRA, all pins initialize as inputs with the pulldown devices active (if enabled by mask option register bit).

Figure 7-2. Port A Pulldown Inhibit Register (PDRA)

7.3.4 Port A LED Drive Capability

The outputs of port A pins 4 through 7 are capable of sinking high current for LED drive capability.

7.3.5 Port A I/O Pin Interrupts

The inputs for the lower four bits of port A can be connected through an OR gate to the IRQ latched input to the CPU by a mask option register bit. When connected as an alternate source of an IRQ interrupt, the port A input pins behave the same as the $\overline{\text{IRQ}}$ pin itself, except that their active state is a logical one or a rising edge. The normal $\overline{\text{IRQ}}$ pin has an active state that is a logical zero or a falling edge depending on the mask option register bit.

If the mask option register bit for edge- and level-sensitive interrupts and the mask option register bit for port A interrupts are both used, the presence of a logic one on any one of the lower four port A pins causes an IRQ interrupt request. If the mask option register bit for edge-sensitive-only interrupts and the mask option register bit for port A interrupts are both used, the occurrence of a rising edge on any one of the PA0–PA3 pins causes an IRQ interrupt request, as long as the other PA0–PA3 pins are at a low level. As long as any one of the PA0 through PA3 IRQ inputs remains at a logic one level, or the $\overline{\text{IRQ}}$ remains at a

logic zero level, the other PA0–PA3 IRQ inputs are effectively ignored. Port interrupts will be generated with the above PA0–PA3 I/O state regardless of whether the port is configured as an input or output.

NOTE: *The BIH and BIL instructions apply only to the level on the \overline{IRQ} pin itself, and not to the internal IRQ input to the CPU. Therefore, BIH and BIL cannot be used to test the state of the lower four port A input pins as a group. Each port A interrupt pin can be tested by reading the port A data register at \$0000.*

7.4 Port B

Port B is a 2-bit bidirectional port that shares one of its pins with the RC oscillator as shown in [Figure 7-3](#). Each port B pin is controlled by the corresponding bits in a data direction register, a data register, and a pulldown register.

The port B data register is located at address \$0001. The port B data direction register (DDRB) is located at address \$0005, and the port B pulldown register (PDRB) is located at address \$0011. Reset clears both the DDRB and the PDRB. The port B data register is unaffected by reset.

7.4.1 Port B Data Register

Each port B I/O pin has a corresponding bit in the port B data register. When a port B pin is programmed as an output, the state of the corresponding data register bit determines the state of the output pin. When a port B pin is programmed as an input, any read of the port B data register returns the logic state of the corresponding I/O pin, and any write to the port B data register is saved in the data register, but not applied to the corresponding I/O pin. Unused bits 2 through 7 are always read as logic zeros, and any write to these bits is ignored. The port B data register is unaffected by reset. The port B data register is indeterminate after initial power-up.

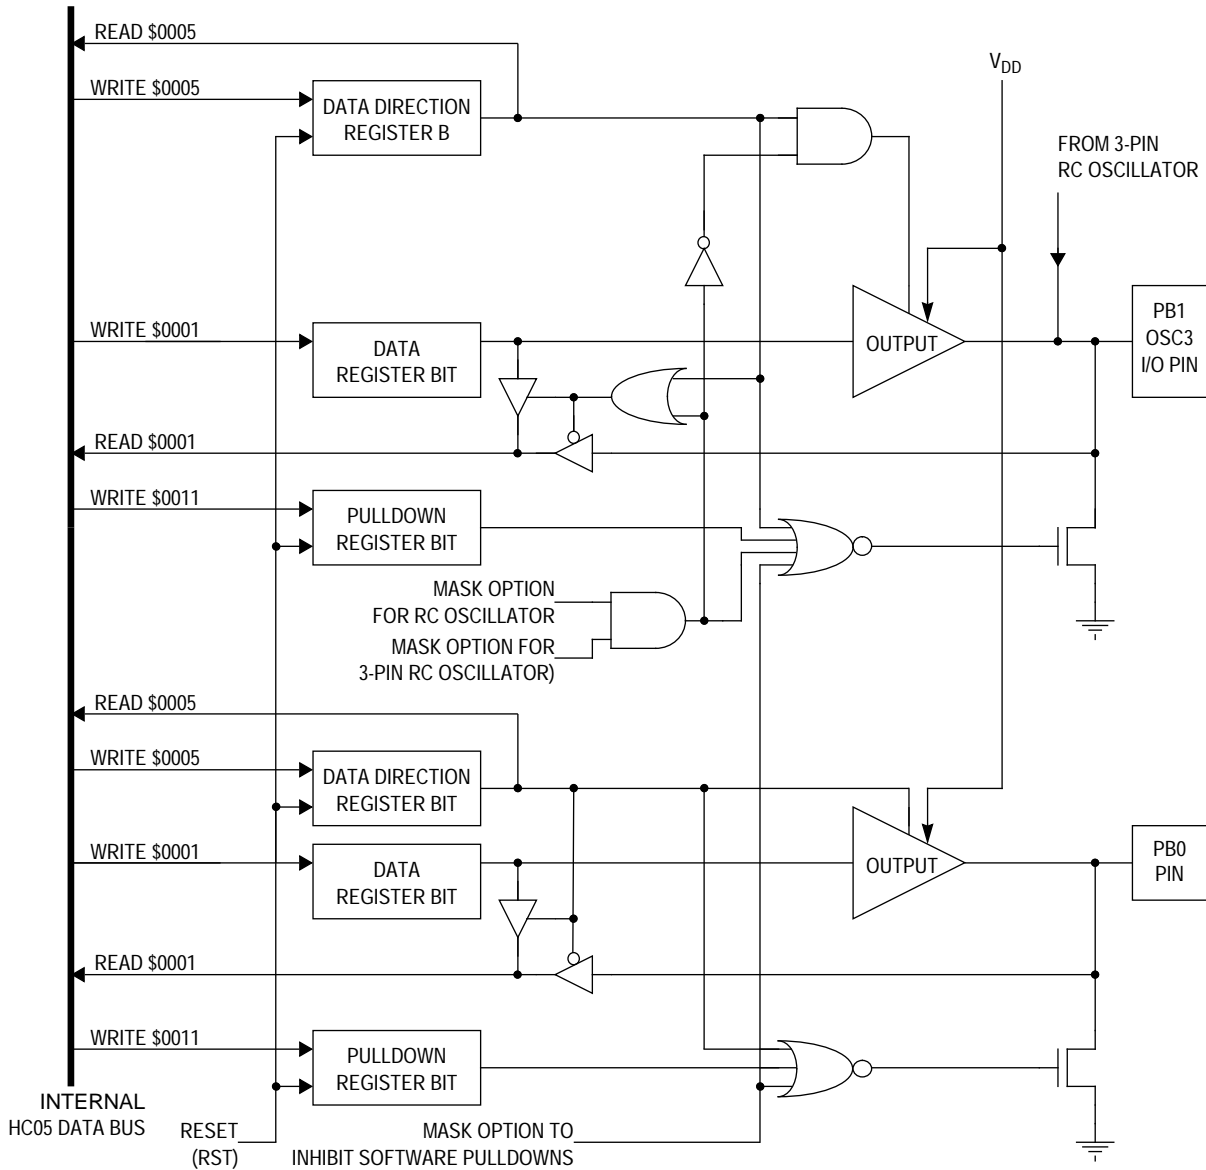

Figure 7-3. Port B I/O Circuitry

7.4.2 Port B Data Direction Register

Each port B I/O pin may be programmed as an input by clearing the corresponding bit in the DDRB or programmed as an output by setting the corresponding bit in the DDRB. When a DDRB bit is set, the corresponding pulldown device is disabled. The DDRB can be accessed at address \$0005. Unused bits 2 through 7 are always read as logic zeros, and any write to these bits is ignored. The DDRB is cleared by reset.

7.4.3 Port B Pulldown Inhibit Register

Each port B I/O pin has a software programmable pulldown device which can be enabled by a mask option register bit. If enabled by a mask option register bit, the software programmable pulldowns are activated by clearing the corresponding bit in the PDRB or disabled by setting the corresponding bit in the PDRB. If disabled by a mask option register bit, all pulldowns are disabled. A pulldown on an I/O pin can be activated only if the I/O pin is programmed as an input.

The PDRB is a write-only register and any reads of location \$0011 return undefined results. Since reset clears both the DDRB and the PDRB, all pins initialize as inputs with the pulldown devices active (if enabled by mask option register bit).

Figure 7-4. Port B Pulldown Inhibit Register (PDRB)

7.4.4 Port B with 3-Pin RC Oscillator

The PB1/OSC3 pin may be used as an output from a 3-pin RC oscillator when the mask option register bit for a 3-pin RC oscillator is used. In this case, the following conditions apply:

- The PB1 data register bit can be used as a read/write storage location without affecting the oscillator. PB1 is unaffected by reset.
- The DDRB1 data direction bit can be used as a read/write storage location without affecting the oscillator. DDRB1 is cleared by reset.
- The software programmable pulldown on PB1/OSC3 is disabled, regardless of the mask option register bit selection for the software programmable pulldowns or the state of PDRB1.

7.5 I/O Port Programming

All I/O pins can be programmed as inputs or outputs, with or without pulldown devices.

7.5.1 Pin Data Direction

The direction of a pin is determined by the state of its corresponding bit in the associated port data direction register (DDR). A pin is configured as an output if its corresponding DDR bit is set to a logic one. A pin is configured as an input if its corresponding DDR bit is cleared to a logic zero.

The data direction bits DDRB0, DDRB1, and DDRA0 through DDRA7 are read/write bits that can be manipulated with read-modify-write instructions. At power-on or reset, all DDRs are cleared, which configures all port pins as inputs. If the mask option register bit for software programmable pulldowns is selected, all pins initially power-up with their software programmable pulldowns enabled.

7.5.2 Output Pin

When an I/O pin is programmed as an output pin, the state of the corresponding data register bit determines the state of the pin. The state of the data register bits can be altered by writing to address \$0000 for port A and address \$0001 for port B. Reads of the corresponding data register bit at address \$0000 or \$0001 return the state of the data register bit, not the state of the I/O pin itself. Therefore, bit manipulation is possible on all pins programmed as outputs.

All pins programmed as outputs have their pulldown devices disabled regardless of the selected mask option register bit for software programmable pulldowns or the state of their PDR bits.

7.5.3 Input Pin

When an I/O pin is programmed as an input pin, the state of the pin can be determined by reading the corresponding data register bit. Any writes to the corresponding data register bit for an input pin is saved by the register bit, but not applied to the corresponding I/O pin until the pin is later programmed to be an output.

If the corresponding bit in the pulldown register is clear (and the mask option register bit for software programmable pulldowns is selected), the input pin also has an activated pulldown device.

Read-modify-write instructions, such as bit manipulation, should not be used on the pulldown registers, since they are write-only.

7.5.4 I/O Pin Transitions

A “glitch” can be generated on an I/O pin when changing it from an input to an output unless the data register is first pre-conditioned to the desired state before changing the corresponding DDR bit from a zero to a one.

If the mask option register bit for software programmable pulldowns is selected, a floating input can be avoided by first clearing the pulldown register bit before changing the corresponding DDR from a one to a zero. This ensures that the pulldown device is activated on the pin as the I/O pin changes from a driven output to a pulled low input.

7.5.5 I/O Pin Truth Tables

Every pin on port A and PB0 on port B may be programmed as an input or an output under software control, as shown in [Table 7-1](#) and [Table 7-2](#). All port I/O pins also may have software programmable pulldown devices selected by a mask option register bit. The PB1/OSC3 pin on port B also can be programmed as an input or an output under software control, but it has special considerations when selected by a mask option register bit as an output for the 3-pin RC oscillator, as shown in [Table 7-3](#). Otherwise, PB1/OSC3 behaves the same as PB0.

8.3.2	Timer Status/Control Register (TSCR) \$08	74
8.4	COP Watchdog Timer	76
8.5	Operating During Stop Mode	76

8.2 Introduction

The timer for this device is an 8-bit ripple counter. The features include timer overflow, power-on reset (POR), real time interrupt, and COP watchdog timer. This timer is powered down in the stop mode to reduce STOP I_{DD} .

As shown in **Figure 8-1**, the timer is driven by the timer clock, NTF1, divided by four (4). NTF1 has the same phase and frequency as the processor bus clock, PH2, but is not stopped by the wait or halt modes. This signal drives an 8-bit ripple counter. The value of this 8-bit ripple counter can be read by the CPU at any time by accessing the timer counter register (TCNTR) at address \$09. A timer overflow function is implemented on the last stage of this counter, giving a possible interrupt at the rate of $f_{OP}/1024$. Two additional stages produce the POR function at $f_{OP}/4064$ or $f_{OP}/16$, followed by two more stages, with the resulting clock ($f_{OP}/16,384$) driving the real time interrupt (RTI) circuit.

The RTI circuit consists of three divider stages with a one-of-four selector. The output of the RTI circuit is further divided by eight to drive the optional COP watchdog timer circuit, which can be enabled by a mask option register bit. The RTI rate selector bits, and the RTI and TOF enable bits and flags are located in the timer control and status register

at location \$08. The clock frequency that drives the RTI circuit is $f_{OP}/2^{14}$ (or $f_{OP}/16384$) with three additional divider stages giving a maximum interrupt period of $f_{OP}/2^{17}$ (or $f_{OP}/131072$).

The power-on cycle clears the entire counter chain and begins clocking the counter. After 4064 or 16 cycles (depending on mask option register bit), the power-on reset circuit is released, which again clears the counter chain and allows the device to come out of reset. At this point, if \overline{RESET} is not asserted, the timer starts counting up from zero and normal device operation begins. If \overline{RESET} is asserted at any time during operation, the counter chain is cleared.

Figure 8-1. Timer Block Diagram

8.3 Timer Registers

The 8-bit timer contains two registers: a timer counter register and a timer status/control register.

8.3.1 Timer Counter Register (TCNTR) \$09

The timer counter register is a read-only register that contains the current value of the 8-bit ripple counter at the beginning of the timer chain. This counter is clocked at f_{OP} divided by 4 and can be used for various functions including a software input capture. Extended time periods can be attained using the TOF function to increment a temporary RAM storage location thereby simulating a 16-bit (or more) counter. The value of each bit of the TCNTR is shown below. This register is cleared by reset.

\$09	Bit 7	6	5	4	3	2	1	Bit 0
Read:	TCR7	TCR6	TCR5	TCR4	TCR3	TCR2	TCR1	TCR0
Write:								
Reset:	0	0	0	0	0	0	0	0

 = Unimplemented

Figure 8-2. Timer Counter Register

8.3.2 Timer Status/Control Register (TSCR) \$08

The TSCR contains the timer interrupt flag, the timer interrupt enable bits, and the real time interrupt rate select bits. Bit 2 and bit 3 are write-only bits that read as logical zeros. Figure 8-3 shows the value of each bit in the TSCR following reset.

\$08	Bit 7	6	5	4	3	2	1	Bit 0
Read:	TOF	RTIF	TOIE	RTIE	0	0	RT1	RT0
Write:					TOFR	RTIFR		
Reset:	0	0	0	0	0	0	1	1

 = Unimplemented

Figure 8-3. Timer Status/Control Register

TOF — Timer Overflow

The TOF is a read-only flag bit that is set when the 8-bit ripple counter rolls over from \$FF to \$00. A timer interrupt request is generated if TOF is set when TOIE is also set. The TOF flag bit is reset by writing a logical one to the TOFR acknowledge bit. Writing to the TOF flag bit has no effect on its value. This bit is cleared by reset.

RTIF — Real Time Interrupt Flag

The RTIF is a read-only flag bit that is set when the output of the chosen (one-of-four selection) real time interrupt stage goes active. A timer interrupt request is generated if RTIF is set when RTIE is also set. The RTIF flag bit is reset by writing a logical one to the RTIFR acknowledge bit. Writing to the RTIF flag bit has no effect on its value. This bit is cleared by reset.

TOIE — Timer Overflow Interrupt Enable

The TOIE is an enable bit that allows generation of a timer interrupt. When the TOIE enable bit is set, the TIMER Interrupt is generated when the TOF flag bit is set. This bit is cleared by reset.

RTIE — Real Time Interrupt Enable

The RTIE is an enable bit that allows the generation of a timer interrupt. When the RTIE enable bit is set and the RTIF flag bit is set, the timer interrupt is generated. The RTIE bit is cleared by reset.

TOFR — Timer Overflow Acknowledge

The TOFR is an acknowledge bit that resets the TOF flag bit. Writing a logical one to the TOFR clears the TOF flag bit. Reading the TOFR always returns a logical zero. This bit is unaffected by reset.

RTIFR — Real Time Interrupt Acknowledge

The RTIFR is an acknowledge bit that resets the RTIF flag bit. Writing a logical one to the RTIFR clears the RTIF flag bit. Reading the RTIFR always returns a logical zero. This bit is unaffected by reset.

RT1:RT0 — Real Time Interrupt Rate Select

The RT0 and RT1 control bits select one-of-four taps for the real time interrupt circuit. **Table 8-1** shows the available interrupt rates with several f_{OP} values. Both the RT0 and RT1 control bits are set by reset, selecting the lowest periodic rate and therefore the maximum time in which to alter these bits if necessary. Care should be taken when altering RT0 and RT1 if the time-out period is imminent or uncertain. If the selected tap is modified during a cycle in which the counter is switching, an RTIF can be missed or an additional RTIF can be generated. To avoid problems, the COP should be cleared just prior to changing RTI taps.

Table 8-1. RTI Rates and COP Reset Times

RT1:RT0	RTI Rate	RTI Period ($f_{OP} = 2 \text{ MHz}$)	COP Timeout Period ($\pm 1 \text{ RTI Period}$)	Minimum COP Timeout Period ($f_{OP} = 2 \text{ MHz}$)
0 0	$f_{OP} \div 2^{14}$	8.2 ms	8 x RTI Period	57.3 ms
0 1	$f_{OP} \div 2^{15}$	16.4 ms	8 x RTI Period	114.7 ms
1 0	$f_{OP} \div 2^{16}$	32.8 ms	8 x RTI Period	229.4 ms
1 1	$f_{OP} \div 2^{17}$	65.5 ms	8 x RTI Period	458.8 ms

8.4 COP Watchdog Timer

The computer operating properly (COP) watchdog timer function is implemented on this device by using the output of the RTI circuit and further dividing it by eight. The minimum COP reset times are listed in [Table 8-1](#).

If the COP circuit times out, an internal reset is generated and the reset vector is fetched. Preventing a COP time out is done by writing a logical zero to the COPC bit at address \$03F0 as shown below. The COPR register is shared with a user EEPROM byte. This address location is not affected by any reset signals. Reading this location returns the user EEPROM byte. When the COPC is cleared, only the final four bits used to count eight RTI cycles are cleared. The COP watchdog timer can be enabled/disabled by a mask option register bit.

Figure 8-4. COPR Watchdog Timer Location

8.5 Operating During Stop Mode

The timer system is cleared when going into stop mode. When STOP is exited by an external interrupt or an external RESET, the internal oscillator resumes, followed by a 16 or 4064 cycle internal processor oscillator stabilization delay. The timer system counter is then cleared and operation resumes. If the STOP instruction is disabled by mask option register bit to create the halt mode, the effects on the timer are as described in [8.6 Operating During Wait Mode](#).

8.6 Operating During Wait Mode

The CPU clock halts during the wait mode, but the timer remains active. If interrupts are enabled, a timer interrupt or custom periodic interrupt causes the processor to exit the wait mode.

Section 9. Personality EEPROM

9.1 Contents

9.2	Introduction	79
9.3	PEEPROM Registers	81
9.3.1	PEEPROM Bit Select Register (PEBSR)	81
9.3.2	PEEPROM Status/Control Register (PESCR)	82
9.4	PEEPROM Programming	86

9.2 Introduction

The MC68HC805K3 contains a 128-bit personality EEPROM (PEEPROM) for storage of variables or user data. These 128 bits are provided as a simple EEPROM array and control logic that requires serial reading of the data. The PEEPROM may be accessed via software programmed into the user EEPROM through two registers that directly interface with the PEEPROM array. The actual implementation of the software varies depending on customer requirements. The PEEPROM array is arranged as 16 bytes (rows) with a separate column select for each bit (column) in a byte. The column select connects the bit to a single sense amplifier as shown in the block diagram of the PEEPROM module in [Figure 9-1](#).

An on-chip charge pump is provided to allow programming and erasure of the Personality EEPROM if the supply voltage to the V_{DD} pin is at least 3.0 Vdc.

NOTE: *Programming and erasure of the personality EEPROM may only be performed if $V_{DD} > 3.0$ Vdc.*

Figure 9-1. Personality EEPROM Block Diagram

Freescale Semiconductor, Inc.

9.3 PEEPROM Registers

Two register locations are used to support the EEPROM array. These are the bit select and status/control registers.

9.3.1 PEEPROM Bit Select Register (PEBSR)

The PEEPROM bit select register is located at \$000E and contains the enable signals for the rows and columns to access the bits in the EEPROM array. The placement of these bits is shown below. The output of this register is connected to two decoders, one for the array column and one for the array row.

A byte in the PEEPROM is defined by the upper four bits in the 7-bit address in the PEBSR (PEB3 through PEB6) and the bit within that byte is defined by the lower three bits in the 7-bit address in the PEBSR (PEB0 through PEB2). The upper bit in the PEBSR (PEB7) may be used as a storage location. All of the bits in the PEBSR register are cleared by reset.

Figure 9-2. PEBSR Select Register

9.3.2 PEEPROM Status/Control Register (PESCR)

The PEEPROM Status/Control Register is located at \$000F and contains 5 user bits, as shown in **Figure 9-3**. Bit 1 is unimplemented and always reads as a logic zero. The states of all bits except PEPCZF and PEDATA are cleared by reset. The PEPCZF is set by reset; and the state of the PEDATA bit following reset is dependent on the stored data in bit 0 of the PEEPROM array.

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	PEDATA	PEBULK	PEPGM (DATA IN)	PEBYTE	CPEN	CPCLK	0	PEPCZF
Write:								
Reset:	1	0	0	0	0	0	0	1

 = Unimplemented

Figure 9-3. PESCR Status/Control Register

PEPCZF — PEEPROM Column Zero Flag

The PEPCZF is a flag bit that is set to a logical one when the first column (COL0) of the EEPROM array is selected. If any other column is selected, the PEPCZF flag bit is cleared. This flag bit can be used to reduce the software code required to access one byte of the PEEPROM. The PEPCZF is set following a reset, since the first column is selected by the reset of the PEBSR. The software code given in **Table 9-1** is suggested for reading one byte from the PEEPROM.

        ; peep_rd loop ends when PEPCZF = 1.
        ; At end of loop, ram contains one row of PEEP data.
    
```

CPCLK — Charge Pump Clock Source

The CPCLK bit is a read/write bit that controls the source of the clock for the charge pump. When the CPCLK bit is set, the charge pump is driven by the PH2 bus clock. When the CPCLK bit is cleared, the charge pump is driven from an internal ring oscillator. The CPCLK bit is cleared when the device is in reset.

In systems where the desired PH2 clock rate is below 1 MHz, the CPCLK bit should be cleared to enable the internal ring oscillator. Otherwise, the charge pump does not attain sufficient program/erase voltage because the clock source is too slow.

CPEN — Charge Pump Enable

The CPEN bit is a read/write bit to control the on-chip charge pump for programming and erasure of the Personality EEPROM. **This charge pump is only intended for use at V_{DD} supply voltages above 3.0 Vdc.** The charge pump is activated when both the CPEN bit is set and one of the program or erase bits is also set (PEPGM, PEBYTE, or PBULK). The charge pump supplies the required programming voltage to the Personality EEPROM array. Once activated, and after startup time t_{CP}, the charge pump continues to operate until all the program and erase bits are cleared.

NOTE: *If the personality EEPROM is read while the CPEN bit is set, the data is unknown.*

The charge pump must always be used to program or erase bits in the Personality EEPROM. The CPEN bit is cleared when the device is in reset.

NOTE: *Setting the CPEN bit can activate the charge pump. However, all the PEPGM, PEBYTE, PEBULK, and CPEN bits must be cleared to deactivate the charge pump. If the charge pump is left running, the overall device I_{DD} current increases.*

PEBYTE — PEEPROM Byte Erase

The PEBYTE bit is a read/write bit to control the switches that apply the internally provided charge pump programming voltage to a row in the PEEPROM array that is to be erased. When the PEBYTE bit is set to a logical one, a logical zero is stored to all bits in the same row of the PEEPROM array, as specified by the upper four bits of the 7-bit address in the PEBSR.

The PEBYTE bit should only be set if the PEPGM and PEBULK bits are cleared. If both the PEBYTE and PEBULK bits are set, the PEEPROM is bulk erased. The PEBYTE bit is cleared when the device is reset.

PEPGM — PEEPROM Program Control

The PEPGM bit is a read/write bit to control the switches that apply the internally provided charge pump programming voltage to the device in the PEEPROM array that is to be programmed. When the PEPGM bit is set to a logical one, a logical one is stored to the PEEPROM array element specified by the address in the PEBSR. Since the state of the PEPGM bit determines the state of the programmed bit in the PEEPROM array, the PEPGM bit is similar to a DATA IN bit.

The PEPGM bit should be set only if the PEBYTE and PEBULK bits are cleared. The PEPGM bit is cleared when the device is reset.

NOTE: *Only one of the PEPGM, PEBYTE, or PEBULK bits should be set at any one time.*

NOTE: *Always clear the PEPGM bit before altering the addressing bits in the PEBSR. Otherwise, intermediate locations may be affected if the programming voltage is present.*

PEBULK — PEEPROM Bulk Erase

The PEBULK bit is a read/write bit to control the switches that apply an internally provided programming voltage to all the bits in the PEEPROM array that are to be erased. When the PEBULK bit is set to a logical one, a logical zero is stored to all bits of the PEEPROM array regardless of the bit address specified in the PEBSR.

The PEBULK bit should only be set if the PEBYTE and PEPGM bits are cleared. If both the PEBYTE and PEBULK bits are set, the personality EEPROM is bulk erased. The PEBULK bit is cleared when the device is reset.

PEDATA — PEEPROM DATA

The PEDATA bit is a read-only bit that reflects the state of the PEEPROM sense amplifier. The state of the PEDATA bit is only meaningful when the PEBYTE, PEPGM, PEBULK, and CPEN control bits are all zero. The state of the PEDATA bit following a reset is dependent on the stored data in bit 0 of the PEEPROM array.

9.4 PEEPROM Programming

The PEEPROM can be programmed using a Motorola programmer or in the user application **if the V_{DD} supply source is at least 3.0 Vdc**. In the latter case, the programming software must be provided in the user EEPROM and use some external pins in either a serial or parallel method for data transfer and/or access. Each bit of the PEEPROM can be programmed as follows:

1. Write the desired bit location to be programmed into the PEBSR located at \$000E.
2. Set the PEPGM and CPEN bits in the PESCR located at \$000F.
3. Wait for a t_{EPGM} time delay.
4. Clear the PEPGM and CPEN bits.

The PEEPROM is then ready to be set up for another bit of data for programming.

The programming of a PEEPROM bit only requires access of that bit through the PEBSR followed by setting the PEPGM and CPEN bits in the PESCR. Do not access any bits that are to be left unprogrammed (erased) until all the PEPGM, PEBYTE, PEBULK, and CPEN bits in the PESCR are cleared. Always clear the PEPGM, PEBYTE, PEBULK, and CPEN bits before altering the PEBSR register.

9.5 PEEPROM Read Access

The contents of the PEEPROM are read by the following sequence:

1. Write the desired bit location to be read into the PEBSR located at \$000E.
2. Read the state of the PEDATA bit in the PESCR located at \$000F.
3. Store the state of the PEDATA bit into RAM or a register.
4. Select another bit by changing the PEBSR.
5. Continue reading and storing the PEDATA bit states until all the required PEEPROM data has been accessed.

Reading the PEEPROM is easiest when each row in the PEEPROM array is mapped to contain one byte of data. Selecting a column zero bit selects the first bit in the row; and incrementing the PEEPROM bit select register (PEBSR) selects the next (column 1) bit from the same row. Incrementing the PEBSR seven more times selects the remaining bits of the row and carries over to select column zero of the next row, thereby setting the column zero flag, PEPCZF in the PESCR. The number of increments per row can be controlled by looping on a test of the PEPCZF flag bit.

The complete array can be easily accessed by starting with \$7F for the PEBSR and decrementing the PEBSR after each access of the PEDATA bit. The decrement sequence can end when the contents of the PEBSR are zero.

NOTE: *One byte of data from the PEEPROM can be re-created in the PEBSR itself. This can be done if the read routine builds the 8-bit data byte in the index register or the accumulator and then transfers that result to the PEBSR when completed. Subsequent reads of the PEBSR quickly yield that retrieved data byte.*

Section 10. User Program EEPROM

10.1 Contents

10.2	Introduction	89
10.3	EEPROM Programming	89
10.4	EEPROM Security	89

10.2 Introduction

The user EEPROM consists of 920 bytes of user EEPROM from \$0020 to \$00BF and \$0100 to \$03F7, and 8 bytes of user vector EEPROM from \$03F8 to \$03FF. The COP reset address is located within the main EEPROM address space at \$03F0. It may be used as a user EEPROM location and is included in the available user EEPROM space previously disclosed.

10.3 EEPROM Programming

The MC68HC805K3 user EEPROM and MOR can only be programmed using the appropriate programming board available from Motorola.

10.4 EEPROM Security

The MC68HC805K3 programmer allows the user to optionally select EEPROM security such that an attempt to enter any non-user operating mode will initiate an automatic bulk erasure of all EEPROM locations including the PEEP. Prior to programming the device, the array is also bulk erased automatically.

11.5	Instruction Set Summary	102

11.2 Introduction

The MCU instruction set has 62 instructions and uses eight addressing modes. The instructions include all those of the M146805 CMOS Family plus one more: the unsigned multiply (MUL) instruction. The MUL instruction allows unsigned multiplication of the contents of the accumulator (A) and the index register (X). The high-order product is stored in the index register, and the low-order product is stored in the accumulator.

11.3 Addressing Modes

The CPU uses eight addressing modes for flexibility in accessing data. The addressing modes provide eight different ways for the CPU to find the data required to execute an instruction. The eight addressing modes are:

- Inherent
- Immediate
- Direct
- Extended
- Indexed, no offset
- Indexed, 8-bit offset
- Indexed, 16-bit offset
- Relative

11.3.1 Inherent

Inherent instructions are those that have no operand, such as return from interrupt (RTI) and stop (STOP). Some of the inherent instructions act on data in the CPU registers, such as set carry flag (SEC) and increment accumulator (INCA). Inherent instructions require no operand address and are one byte long.

11.3.2 Immediate

Immediate instructions are those that contain a value to be used in an operation with the value in the accumulator or index register. Immediate instructions require no operand address and are two bytes long. The opcode is the first byte, and the immediate data value is the second byte.

11.3.3 Direct

Direct instructions can access any of the first 256 memory locations with two bytes. The first byte is the opcode, and the second is the low byte of the operand address. In direct addressing, the CPU automatically uses \$00 as the high byte of the operand address.

11.3.4 Extended

Extended instructions use three bytes and can access any address in memory. The first byte is the opcode; the second and third bytes are the high and low bytes of the operand address.

When using the Motorola assembler, the programmer does not need to specify whether an instruction is direct or extended. The assembler automatically selects the shortest form of the instruction.

11.3.5 Indexed, No Offset

Indexed instructions with no offset are 1-byte instructions that can access data with variable addresses within the first 256 memory locations. The index register contains the low byte of the effective address of the operand. The CPU automatically uses \$00 as the high byte, so these instructions can address locations \$0000–\$00FF.

Indexed, no offset instructions are often used to move a pointer through a table or to hold the address of a frequently used RAM or I/O location.

11.3.6 Indexed, 8-Bit Offset

Indexed, 8-bit offset instructions are 2-byte instructions that can access data with variable addresses within the first 511 memory locations. The CPU adds the unsigned byte in the index register to the unsigned byte following the opcode. The sum is the effective address of the operand. These instructions can access locations \$0000–\$01FE.

Indexed 8-bit offset instructions are useful for selecting the kth element in an n-element table. The table can begin anywhere within the first 256 memory locations and could extend as far as location 510 (\$01FE). The k value is typically in the index register, and the address of the beginning of the table is in the byte following the opcode.

11.3.7 Indexed, 16-Bit Offset

Indexed, 16-bit offset instructions are 3-byte instructions that can access data with variable addresses at any location in memory. The CPU adds the unsigned byte in the index register to the two unsigned bytes following the opcode. The sum is the effective address of the operand. The first byte after the opcode is the high byte of the 16-bit offset; the second byte is the low byte of the offset.

Indexed, 16-bit offset instructions are useful for selecting the kth element in an n-element table anywhere in memory.

As with direct and extended addressing, the Motorola assembler determines the shortest form of indexed addressing.

11.3.8 Relative

Relative addressing is only for branch instructions. If the branch condition is true, the CPU finds the effective branch destination by adding the signed byte following the opcode to the contents of the program counter. If the branch condition is not true, the CPU goes to the next instruction. The offset is a signed, two's complement byte that gives a branching range of -128 to $+127$ bytes from the address of the next location after the branch instruction.

When using the Motorola assembler, the programmer does not need to calculate the offset, because the assembler determines the proper offset and verifies that it is within the span of the branch.

11.4 Instruction Types

The MCU instructions fall into the following five categories:

- Register/Memory Instructions
- Read-Modify-Write Instructions
- Jump/Branch Instructions
- Bit Manipulation Instructions
- Control Instructions

11.4.1 Register/Memory Instructions

These instructions operate on CPU registers and memory locations. Most of them use two operands. One operand is in either the accumulator or the index register. The CPU finds the other operand in memory.

Table 11-1. Register/Memory Instructions

Instruction	Mnemonic
Add Memory Byte and Carry Bit to Accumulator	ADC
Add Memory Byte to Accumulator	ADD
AND Memory Byte with Accumulator	AND
Bit Test Accumulator	BIT
Compare Accumulator	CMP
Compare Index Register with Memory Byte	CPX
EXCLUSIVE OR Accumulator with Memory Byte	EOR
Load Accumulator with Memory Byte	LDA
Load Index Register with Memory Byte	LDX
Multiply	MUL
OR Accumulator with Memory Byte	ORA
Subtract Memory Byte and Carry Bit from Accumulator	SBC
Store Accumulator in Memory	STA
Store Index Register in Memory	STX
Subtract Memory Byte from Accumulator	SUB

11.4.2 Read-Modify-Write Instructions

These instructions read a memory location or a register, modify its contents, and write the modified value back to the memory location or to the register.

NOTE: *Do not use read-modify-write operations on write-only registers.*

Table 11-2. Read-Modify-Write Instructions

Instruction	Mnemonic
Arithmetic Shift Left (Same as LSL)	ASL
Arithmetic Shift Right	ASR
Bit Clear	BCLR ⁽¹⁾
Bit Set	BSET ⁽¹⁾
Clear Register	CLR
Complement (One's Complement)	COM
Decrement	DEC
Increment	INC
Logical Shift Left (Same as ASL)	LSL
Logical Shift Right	LSR
Negate (Two's Complement)	NEG
Rotate Left through Carry Bit	ROL
Rotate Right through Carry Bit	ROR
Test for Negative or Zero	TST ⁽²⁾

1. Unlike other read-modify-write instructions, BCLR and BSET use only direct addressing.
2. TST is an exception to the read-modify-write sequence because it does not write a replacement value.

11.4.3 Jump/Branch Instructions

Jump instructions allow the CPU to interrupt the normal sequence of the program counter. The unconditional jump instruction (JMP) and the jump-to-subroutine instruction (JSR) have no register operand. Branch instructions allow the CPU to interrupt the normal sequence of the program counter when a test condition is met. If the test condition is not met, the branch is not performed.

The BRCLR and BRSET instructions cause a branch based on the state of any readable bit in the first 256 memory locations. These 3-byte instructions use a combination of direct addressing and relative addressing. The direct address of the byte to be tested is in the byte following the opcode. The third byte is the signed offset byte. The CPU finds the effective branch destination by adding the third byte to the program counter if the specified bit tests true. The bit to be tested and its condition (set or clear) is part of the opcode. The span of branching is from -128 to $+127$ from the address of the next location after the branch instruction. The CPU also transfers the tested bit to the carry/borrow bit of the condition code register.

Table 11-3. Jump and Branch Instructions

Instruction	Mnemonic
Branch if Carry Bit Clear	BCC
Branch if Carry Bit Set	BCS
Branch if Equal	BEQ
Branch if Half-Carry Bit Clear	BHCC
Branch if Half-Carry Bit Set	BHCS
Branch if Higher	BHI
Branch if Higher or Same	BHS
Branch if $\overline{\text{IRQ}}$ Pin High	BIH
Branch if $\overline{\text{IRQ}}$ Pin Low	BIL
Branch if Lower	BLO
Branch if Lower or Same	BLS
Branch if Interrupt Mask Clear	BMC
Branch if Minus	BMI
Branch if Interrupt Mask Set	BMS
Branch if Not Equal	BNE
Branch if Plus	BPL
Branch Always	BRA
Branch if Bit Clear	BRCLR
Branch Never	BRN
Branch if Bit Set	BRSET
Branch to Subroutine	BSR
Unconditional Jump	JMP
Jump to Subroutine	JSR

11.4.4 Bit Manipulation Instructions

The CPU can set or clear any writable bit in the first 256 bytes of memory, which includes I/O registers and on-chip RAM locations. The CPU can also test and branch based on the state of any bit in any of the first 256 memory locations.

Table 11-4. Bit Manipulation Instructions

Instruction	Mnemonic
Bit Clear	BCLR
Branch if Bit Clear	BRCLR
Branch if Bit Set	BRSET
Bit Set	BSET

11.4.5 Control Instructions

These instructions act on CPU registers and control CPU operation during program execution.

Table 11-5. Control Instructions

Instruction	Mnemonic
Clear Carry Bit	CLC
Clear Interrupt Mask	CLI
No Operation	NOP
Reset Stack Pointer	RSP
Return from Interrupt	RTI
Return from Subroutine	RTS
Set Carry Bit	SEC
Set Interrupt Mask	SEI
Stop Oscillator and Enable $\overline{\text{IRQ}}$ Pin	STOP
Software Interrupt	SWI
Transfer Accumulator to Index Register	TAX
Transfer Index Register to Accumulator	TXA
Stop CPU Clock and Enable Interrupts	WAIT

Section 12. Electrical Specifications

12.1 Contents

12.2	Maximum Ratings	109
12.3	Operating Range	110
12.4	Thermal Characteristics	110
12.5	5.0 Volt DC Electrical Characteristics	111
12.6	3.0 Volt DC Electrical Characteristics	112
12.7	5.0 Volt Control Timing	113
12.8	3.0 Volt Control Timing	114

12.2 Maximum Ratings

Maximum ratings are the extreme limits to which the MCU can be exposed without permanently damaging it.

The MCU contains circuitry to protect the inputs against damage from high static voltages; however, do not apply voltages higher than those shown in the table below. Keep V_{IN} and V_{OUT} within the range $V_{SS} \leq (V_{IN} \text{ or } V_{OUT}) \leq V_{DD}$. Connect unused inputs to the appropriate voltage level, either V_{SS} or V_{DD} .

Rating	Symbol	Value	Unit
Supply Voltage	V_{DD}	-0.3 to + 7.0	V
Input Voltage	V_{IN}	$V_{SS} - 0.3$ to $V_{DD} + 0.3$	V
Storage Temperature Range	T_{STG}	-65 to + 150	°C

NOTE: This device is not guaranteed to operate properly at the maximum ratings. Refer to [12.5 5.0 Volt DC Electrical Characteristics¹](#) and [12.6 3.0 Volt DC Electrical Characteristics¹](#) for guaranteed operating conditions.

12.3 Operating Range

Characteristic	Symbol	Value	Unit
Operating Temperature Range MC68HC805K3 (Standard) MC68HC805K3 (Extended)	T_A	T_L to T_H 0 to +70 -40 to +85	°C
Supply Voltage Range for Internal Charge Pump Operation	V_{DDCP}	3.0 to 5.5	V

12.4 Thermal Characteristics

Characteristic	Symbol	Value	Unit
Thermal Resistance PDIP SOIC	θ_{JA}	100 140	°C/W

12.5 5.0 Volt DC Electrical Characteristics¹

Characteristic	Symbol	Min	Typ	Max	Unit
Output High Voltage ($I_{LOAD} = -0.8$ mA) PA7–PA0, PB1/OSC3, PB0	V_{OH}	$V_{DD} - 0.8$	—	—	V
Output Low Voltage PA3–PA0, PB1/OSC3, PB0 ($I_{LOAD} = 1.6$ mA) PA7–PA4 ($I_{LOAD} = 8.0$ mA)	V_{OL}	— —	— —	0.4 0.4	V

Section 13. Mechanical Specifications

13.1 Contents

13.2	Introduction	115
13.3	Dual-In-Line Package (Case 648)	116
13.4	Small Outline Integrated Circuit (Case 751)	116

13.2 Introduction

The MC68HC805K3 is available in the following packages:

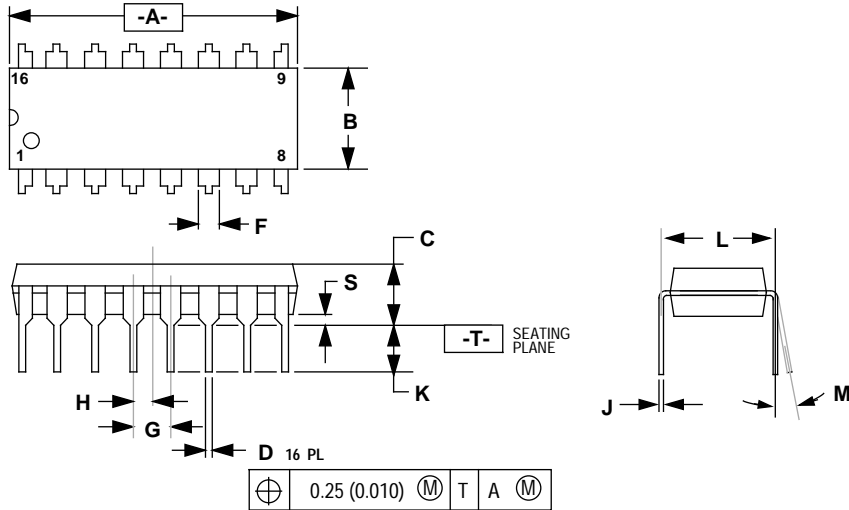

- 648 — Plastic dual in-line package (PDIP)
- 751 — Small outline integrated circuit (SOIC)

The following figures show the latest packages at the time of this publication. To make sure that you have the latest package specifications, contact one of the following:

- Local Motorola Sales Office
- Motorola Mfax
 - Phone 602-244-6609
 - EMAIL rmfax0@email.sps.mot.com
- Worldwide Web (wwweb) at <http://design-net.com>

Follow Mfax or wwweb on-line instructions to retrieve the current mechanical specifications.

RoHS-compliant and/or Pb-free versions of Freescale products have the functionality and electrical characteristics of their non-RoHS-compliant and/or non-Pb-free counterparts. For further information, see <http://www.freescale.com> or contact your Freescale sales representative.

For information on Freescale's Environmental Products program, go to <http://www.freescale.com/epp>.

Information in this document is provided solely to enable system and software implementers to use Freescale Semiconductor products. There are no express or implied copyright licenses granted hereunder to design or fabricate any integrated circuits or integrated circuits based on the information in this document. Freescale Semiconductor reserves the right to make changes without further notice to any products herein. Freescale Semiconductor makes no warranty, representation or guarantee regarding the suitability of its products for any particular purpose, nor does Freescale Semiconductor assume any liability arising out of the application or use of any product or circuit, and specifically disclaims any and all liability, including without limitation consequential or incidental damages. "Typical" parameters which may be provided in Freescale Semiconductor data sheets and/or specifications can and do vary in different applications and actual performance may vary over time. All operating parameters, including "Typicals" must be validated for each customer application by customer's technical experts. Freescale Semiconductor does not convey any license under its patent rights nor the rights of others. Freescale Semiconductor products are not designed, intended, or authorized for use as components in systems intended for surgical implant into the body, or other applications intended to support or sustain life, or for any other application in which the failure of the Freescale Semiconductor product could create a situation where personal injury or death may occur. Should Buyer purchase or use Freescale Semiconductor products for any such unintended or unauthorized application, Buyer shall indemnify and hold Freescale Semiconductor and its officers, employees, subsidiaries, affiliates, and distributors harmless against all claims, costs, damages, and expenses, and reasonable attorney fees arising out of, directly or indirectly, any claim of personal injury or death associated with such unintended or unauthorized use, even if such claim alleges that Freescale Semiconductor was negligent regarding the design or manufacture of the part.
